

Search Engines

Information Retrieval in Practice

IR and Search Engines

Information Retrieval

Relevance

-Effective ranking

Evaluation

-Testing and measuring

Information needs

-User interaction

Search Engines

Performance

-Efficient search and indexing

Incorporating new data

-Coverage and freshness

Scalability

-Growing with data and users

Adaptability

-Tuning for applications

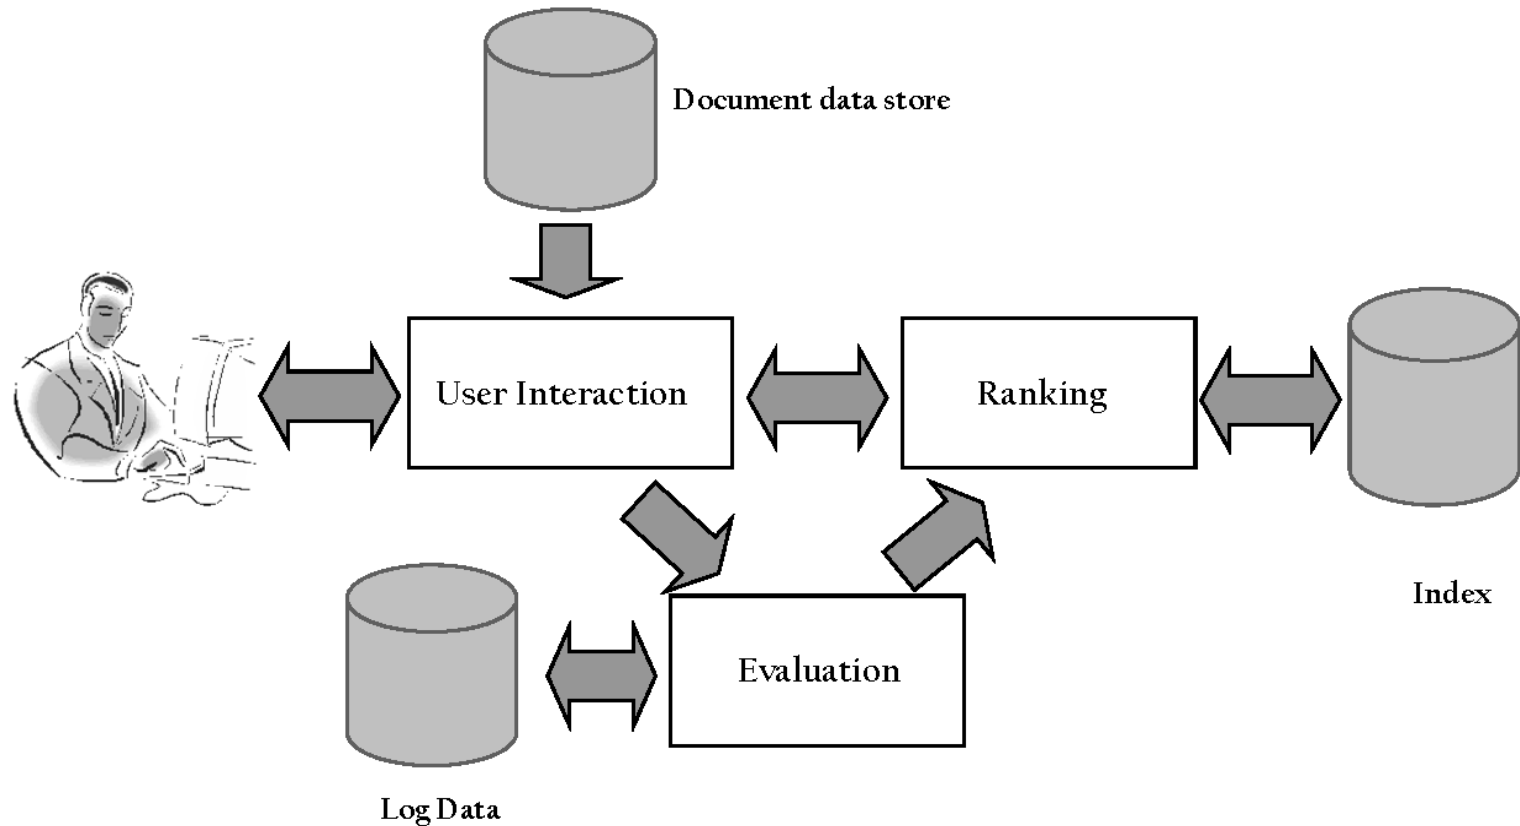

Specific problems

-e.g. Spam, Advertising

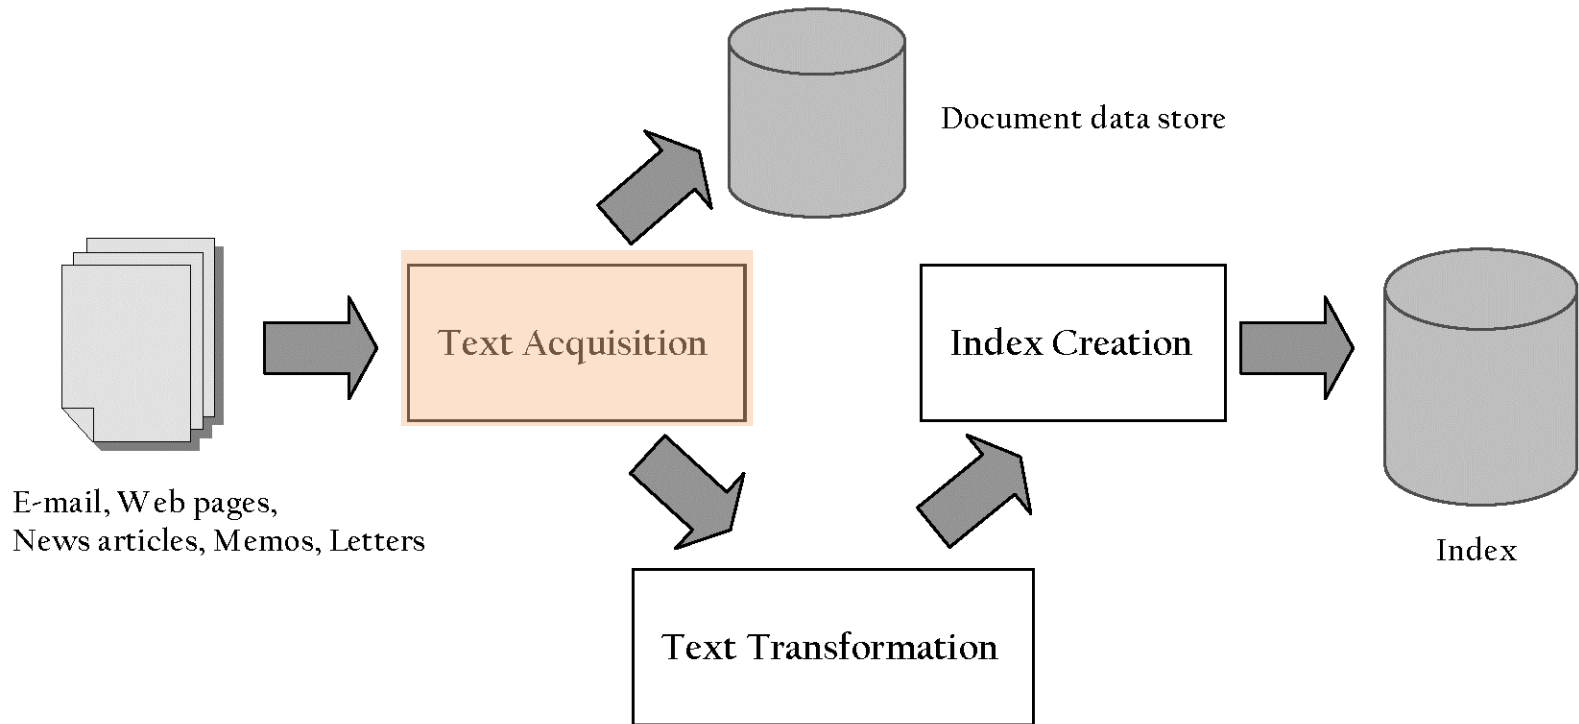

Search Engine Architecture

- A software architecture consists of software components, the interfaces provided by those components, and the relationships between them
 - describes a system at a particular level of abstraction
- Architecture of a search engine determined by 2 requirements
 - effectiveness (quality of results) and efficiency (response time and throughput)

Query Process

Indexing Process

Details: Text Acquisition

- Crawler
 - Identifies and acquires documents for search engine
 - Many types – web, enterprise, desktop
 - Web crawlers follow *links* to find documents
 - Must efficiently find huge numbers of web pages (*coverage*) and keep them up-to-date (*freshness*)
 - Single site crawlers for *site search*
 - *Topical* or *focused* crawlers for vertical search
 - *Document* crawlers for enterprise and desktop search
 - Follow links and scan directories

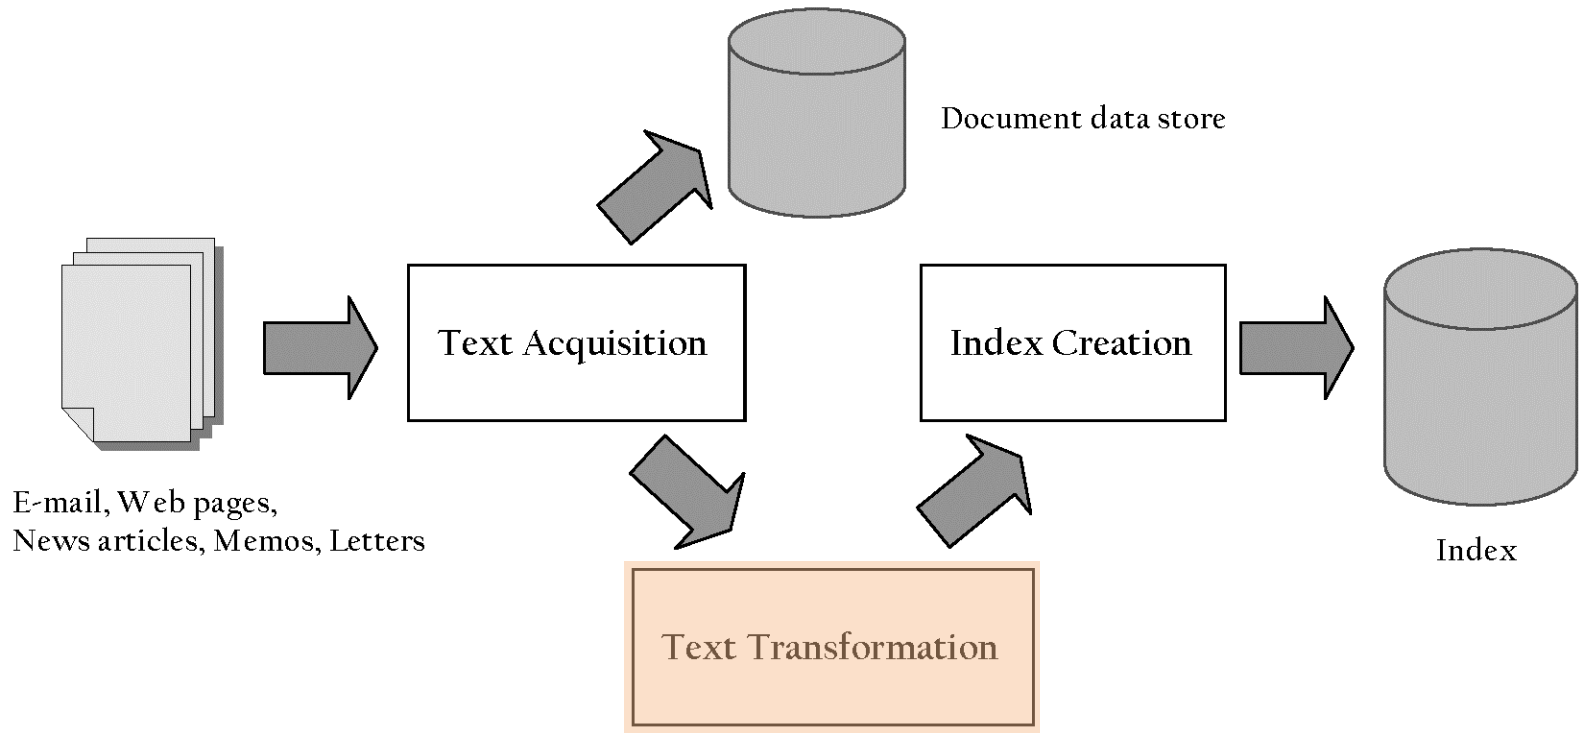

Text Acquisition

- Feeds
 - Real-time streams of documents
 - e.g., web feeds for news, blogs, video, radio, TV
 - RSS is common standard
 - RSS “reader” can provide new XML documents to search engine
- Conversion
 - Convert variety of documents into a consistent text plus metadata format
 - e.g. HTML, XML, Word, PDF, etc. → XML
 - Convert text encoding for different languages
 - Using a Unicode standard like UTF-8

Text Acquisition

- Document data store
 - Stores text, metadata, and other related content for documents
 - Metadata is information about document such as type and creation date
 - Other content includes links, anchor text
 - Provides fast access to document contents for search engine components
 - e.g. result list generation
 - Could use relational database system
 - More typically, a simpler, more efficient storage system is used due to huge numbers of documents

Indexing Process

Text Transformation

- Parser
 - Processing the sequence of text *tokens* in the document to recognize structural elements
 - e.g., titles, links, headings, etc.
 - *Tokenizer* recognizes “words” in the text
 - must consider issues like capitalization, hyphens, apostrophes, non-alpha characters, separators
 - *Markup languages* such as HTML, XML often used to specify structure
 - *Tags* used to specify document *elements*
 - E.g., <h2> Overview </h2>
 - Document parser uses *syntax* of markup language (or other formatting) to identify structure

Text Transformation

- Stopping
 - Remove common words
 - e.g., “and”, “or”, “the”, “in”
 - Some impact on efficiency and effectiveness
 - Can be a problem for some queries
- Stemming
 - Group words derived from a common *stem*
 - e.g., “computer”, “computers”, “computing”, “compute”
 - Usually effective, but not for all queries
 - Benefits vary for different languages

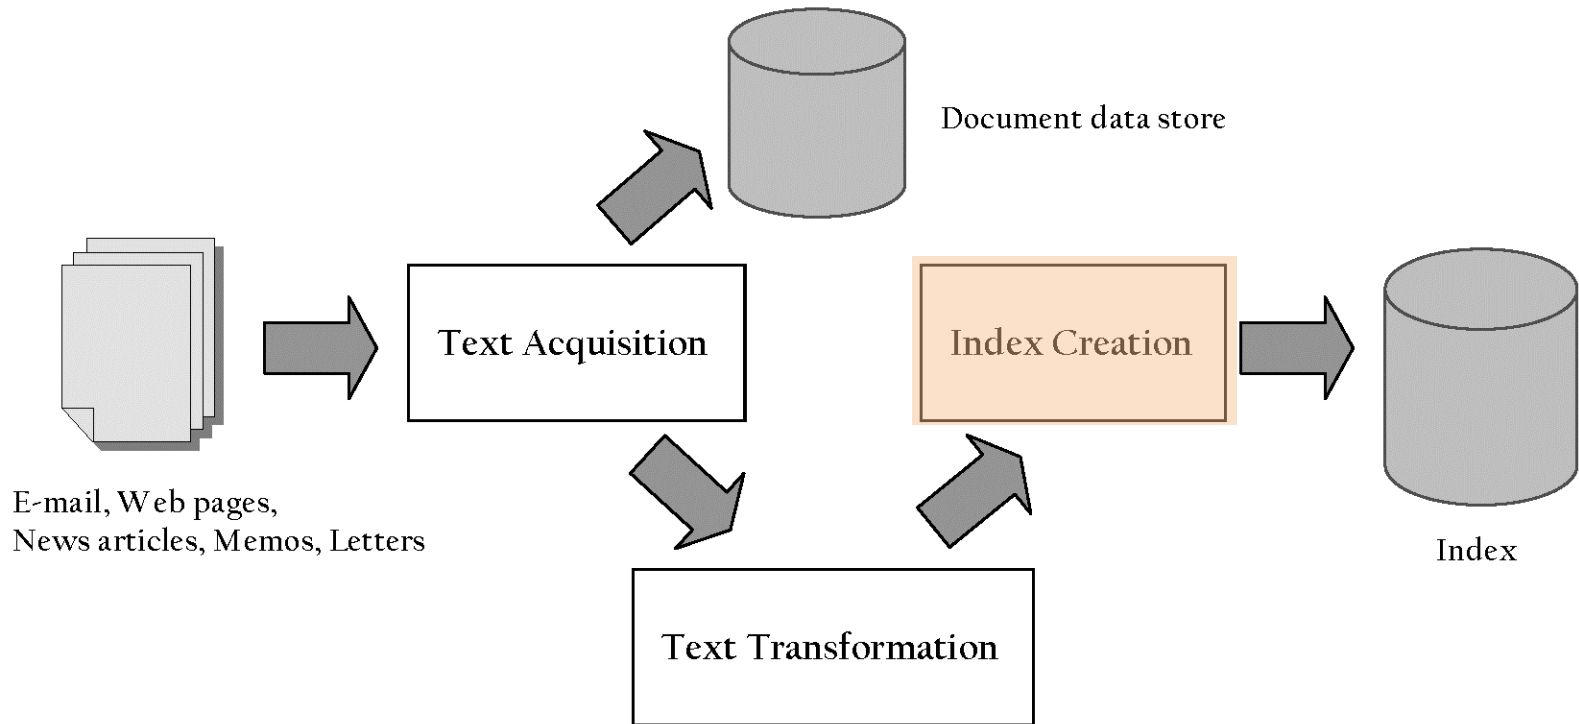

Text Transformation

- Link Analysis
 - Makes use of *links* and *anchor text* in web pages
 - Link analysis identifies *popularity* and *community* information
 - e.g., PageRank
 - Anchor text can significantly enhance the representation of pages pointed to by links
 - Significant impact on web search
 - Less importance in other applications

Text Transformation

- Information Extraction
 - Identify classes of index terms that are important for some applications
 - e.g., *named entity recognizers* identify classes such as *people, locations, companies, dates*, etc.
- Classifier
 - Identifies class-related metadata for documents or part of documents
 - i.e., assigns labels to documents
 - Topics, reading levels, sentiment, genre
 - Spam vs. non-spam
 - Non-content parts of documents e.g. advertisements
 - Use depends on application

Indexing Process

Index Creation

- Document Statistics
 - Gathers counts and positions of words and other features
 - Used in ranking algorithm
- Weighting
 - Computes weights for index terms
 - Used in ranking algorithm
 - e.g., *tf.idf* weight
 - Combination of *term frequency* in document and *inverse document frequency* in the collection

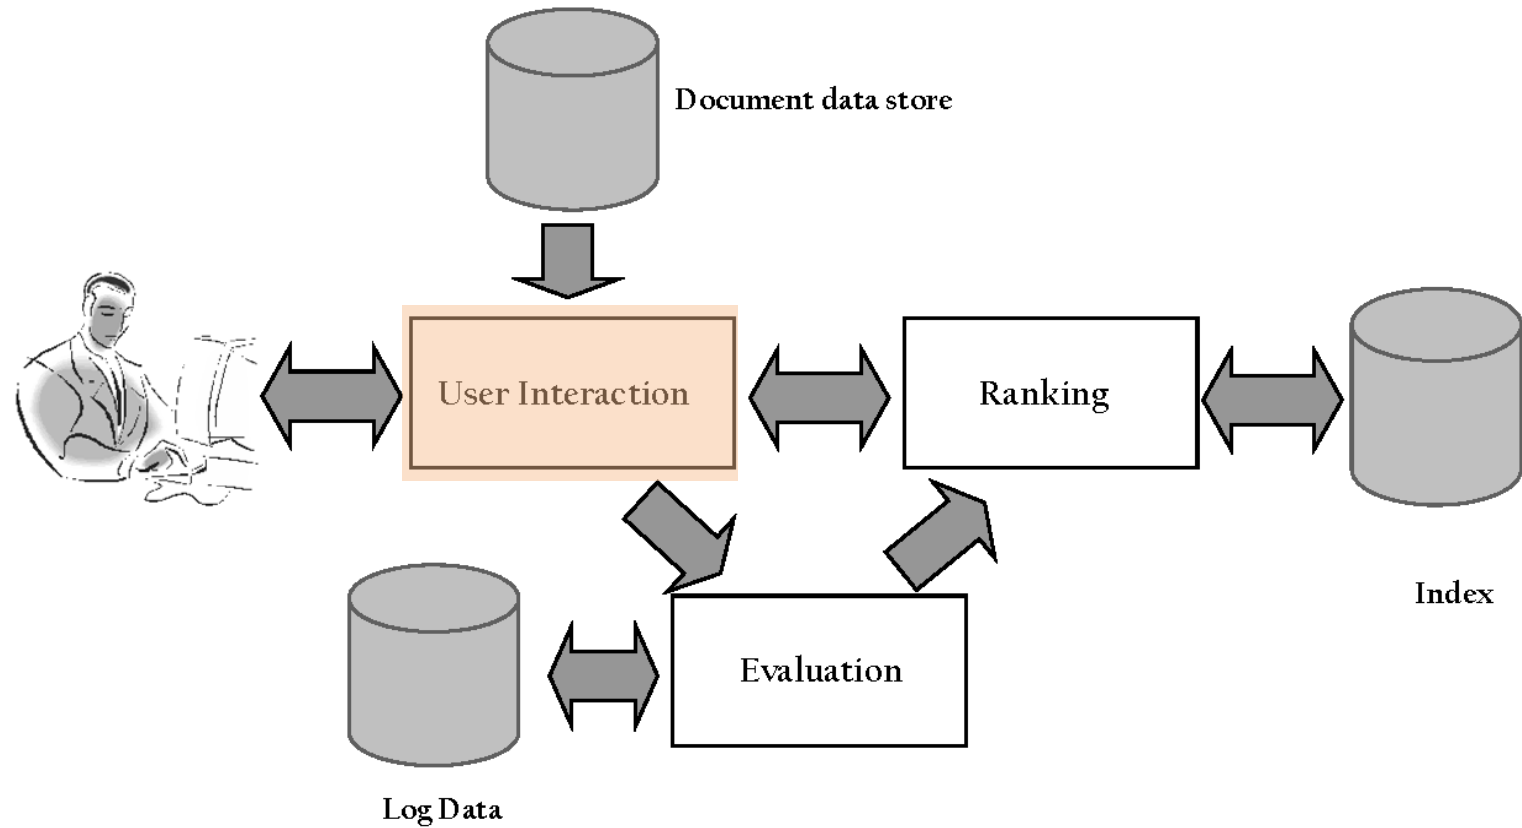

Index Creation

- Inversion
 - Core of indexing process
 - Converts document-term information to term-document for indexing
 - Difficult for very large numbers of documents
 - Format of inverted file is designed for fast query processing
 - Must also handle updates
 - Compression used for efficiency

Distributed Index Creation

- Indexing billions of documents, and updating indexes with changes and new documents is a massive task
- Thousands of processors used in parallel are required
- Dominant distributed programming framework is MapReduce (a.k.a. Hadoop)
 - large scale processing of data-sets on clusters of commodity hardware

Query Process

User Interaction

- Query input
 - Provides interface and parser for *query language*
 - Most web queries are just text
 - *Query completion* can be used to simplify input
 - Query language used to describe complex queries
 - Using operators (e.g., quotes, OR, -, number ranges)
 - There are more complicated query languages
 - e.g., Boolean queries, Indri and Galago query languages
 - Combine content and structure specifications
 - Designed for search “experts” or for the target language for *query transformation*

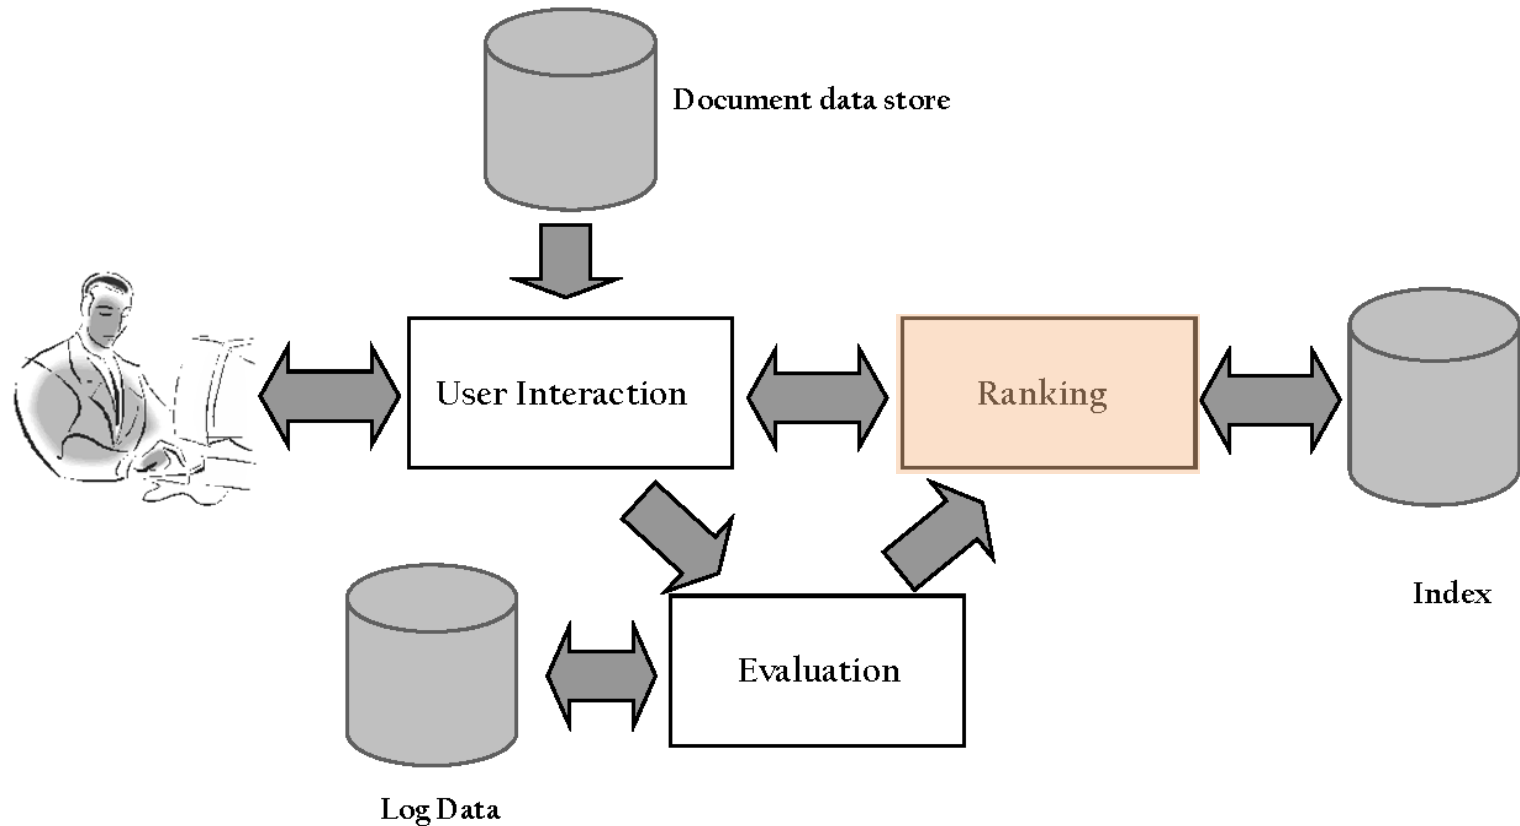

User Interaction

- Query transformation
 - Improves initial query, both before and after initial search
 - Includes text transformation techniques used for documents
 - *Spell checking* and *query suggestion* provide alternatives to original query
 - *Query expansion* and *relevance feedback* modify the original query with additional terms

User Interaction

- Results output
 - Constructs the display of ranked documents for a query
 - *Aggregates* results from multiple verticals
 - e.g., web pages, news, images, maps, knowledge bases
 - Generates *snippets* to show how queries match documents
 - Can *highlight* important words and phrases
 - Retrieves appropriate *advertising* in many applications
 - May provide *clustering* and other visualization tools

Query Process

Ranking

- Scoring
 - Calculates scores for documents using a ranking algorithm
 - Core component of search engine
 - Basic form of score is $\sum q_i d_i$
 - q_i and d_i are query and document term weights for term i
 - Many variations of ranking algorithms and retrieval models

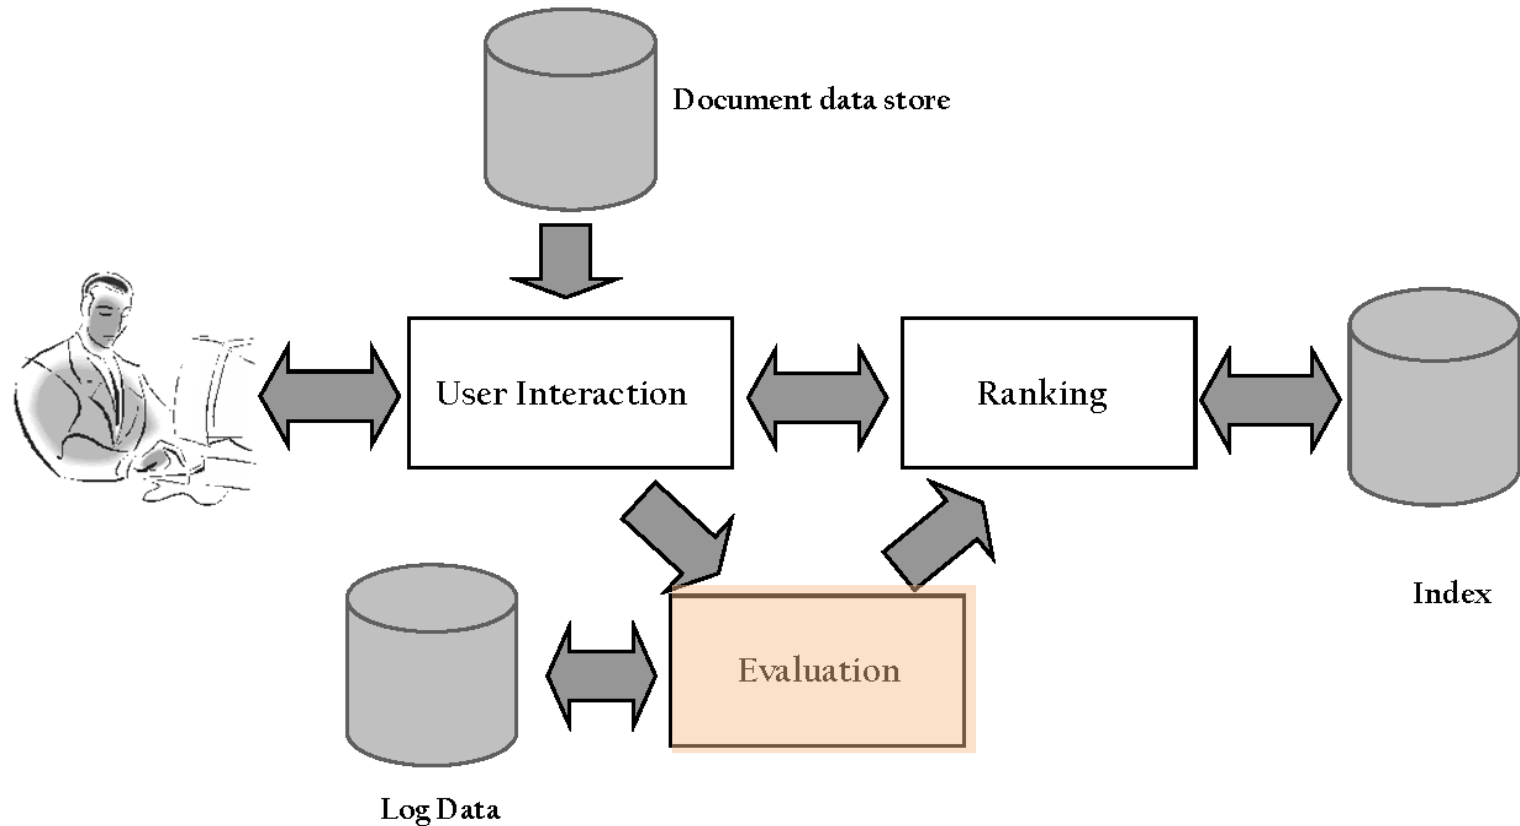

Ranking

- Performance optimization
 - Designing ranking algorithms for efficient processing
 - *Term-at-a-time* (TAAT) vs. *document-at-a-time* (DAAT) processing
 - TAAT used in many research systems,
 - DAAT used in commercial search engines
 - *Safe* vs. *unsafe* optimizations

Distributed Search

- Index Distribution
 - Distributes indexes across multiple computers and/or multiple sites
 - Essential for fast query processing with large numbers of documents
 - Many variations
 - Document distribution, replication, caching
- *Distributed IR or meta-search* involves search across multiple sites

Query Process

Evaluation

- Logging
 - Logging user queries and interaction is crucial for improving search effectiveness and efficiency
 - *Query logs* and *clickthrough data* used for query suggestion, spell checking, query caching, ranking, advertising search, and other components
- Ranking analysis
 - Measuring and tuning ranking effectiveness
- Performance analysis
 - Measuring and tuning system efficiency

How Does It *Really* Work?

- This course explains these components of a search engine in more detail
- Often many possible approaches and techniques for a given component
 - Focus is on the most important alternatives
 - i.e., explain a small number of approaches in detail rather than many approaches
 - Alternatives described in references and in sources on the web

Topics

- Overview
- Architecture of a search engine
- *Data acquisition*
- Text representation
- Indexing
- Query processing
- Ranking
- Evaluation
- Classification and clustering
